

Constructing scatter graphs

Task A: Plotting bivariate data on a scatter graph

1) The table shows weather data from Bradford, for five months in 2021.

Plot this data on a **scatter graph**.

Month	Total rainfall (mm)	Total sunshine (hours)
Feb	100	66
Apr	16	216
Jun	22	173
Aug	61	126
Oct	93	86

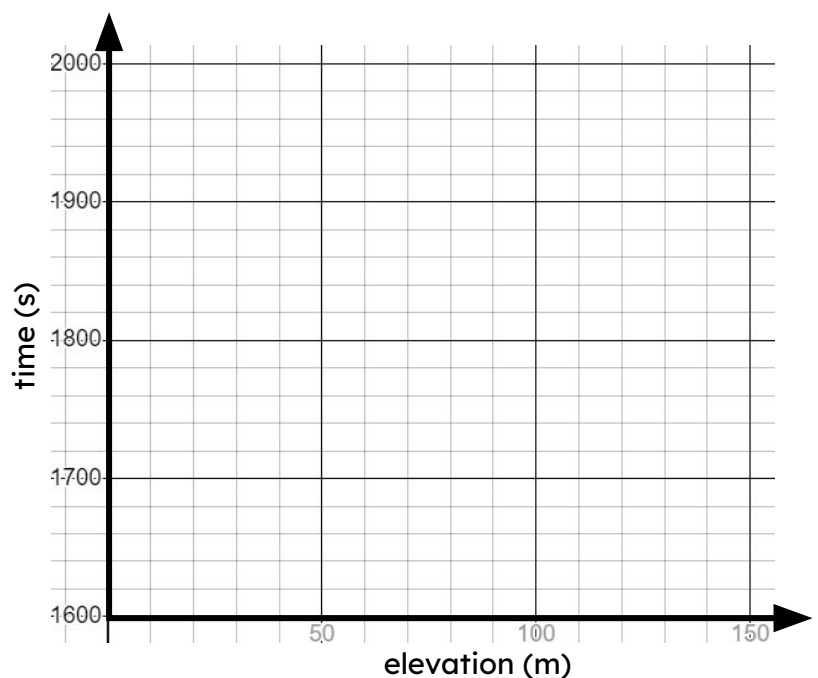

2) Jacob runs a series of long-distance races.

For each race, he records his time and the elevation (steepness) of the course.

Plot Jacob's data on the **scatter graph**.

elevation (m)	time (s)
51	1756
4	1644
35	1735
115	1911
96	1870

Task B: Deciding which axis to use for each variable

- 1) For each pair of **bivariate** data, determine which is the **independent** variable and which is the **dependent** variable.

Example: ice cream sales *dependent*
 maximum temperature of day *independent*

- a) amount of water in a kettle (ml)
 time it take for the kettle to boil (s)
- b) time it takes to complete a running course (s)
 steepness of the running course (m)
- c) age of a child (years)
 height of the child (m)
- d) number of floods reported in a month
 amount of rainfall in the month (mm)

- 2) The data below shows the age and heights for a sample of six children.
Plot the data on a **scatter graph**.

ages (years)	height (cm)
2	81
3	91
5	112
6	120
7	124
11	138
