

Checking understanding of the mean

Task A: Distributing evenly

1) Match up the diagrams. You will need to draw your own original distribution and evenly distributed diagrams on the blank cards.

2) Two crates have been filled with packages for delivery. The driver wants the crates to be evenly distributed with packages. One crate has 18 packages and the other has 12 packages. How would the driver make the crates even?

Take 3 out of the crate with 18 and put them in the crate of 12. That way they both have 15 packages.

3) The batter for three cakes has been split across three tins. The first tin has 1 kg of batter, the second has 1.2 kg of batter and the third has 1.4 kg of batter.

To get 3 cakes the same depth there needs to be the same weight of batter in each tin.

How much batter should there be in each tin?

There should be 1.2 kg of batter in each tin.

4) A group of friends have collected some conkers and shared them equally among themselves.

a) There are five friends and they have 6 conkers each. How many conkers were collected altogether? *30 conkers would have been collected.*

b) Another friend joins them but they don't find any more conkers. How many conkers would they each have if they share them equally now?

5 conkers each

Task B: Calculating the mean

1) Calculate the mean for the following sets of data:

2) Calculate the mean, given the following information:

a) 8000 data points have a total of 26 000

$$26\ 000 \div 8000 = 3.25$$

b) 2400 data points have a total of 15 600

$$15\ 600 \div 2400 = 6.5$$

c) a data set which has a total of 42 000 across 2500 data points

$$42\ 000 \div 2500 = 16.8$$

3) Match the total with the data set, fill in the missing spaces.

Total = 140

11 values, mean of 13

Total = 120

25 values, mean of 6

Total = 150

28 values, mean of 5

Total = 143

24 values, mean of 5
